

Dear Hiring Manager,

I am interested in ING OneApp not only as an Android developer, but also as someone who has used banking apps across different markets for years. After experiencing major banking applications in Turkey, the US, and Europe, I see mobile banking as something that can evolve from a transactional app into a broader financial control center for users.

Professionally, I have worked on Android applications where the mobile app was part of a wider operational system rather than just a standalone interface. At VBM and AKTEK, this included building Android features connected to backend services, process monitoring tools, real-time operational data, and internal visibility workflows. One example was an Android monitoring application around UiPath Orchestrator, an enterprise automation platform used to manage robotic process automation workflows, where the app consumed REST APIs, displayed process status and execution data, and helped make failures easier to detect and investigate.

Outside of my professional work, I have continued applying the same system-oriented approach in my own Android projects. In WhoConnected, I turned the idea of local network visibility into a working architecture: a Raspberry Pi running a Node.js API, nmap-based device discovery, REST communication through Retrofit, and a Jetpack Compose Android interface structured with MVVM. This helped me practice turning a technical problem into clear system boundaries, data flow, and a usable mobile experience.

What makes this role meaningful to me is that banking apps are part of people's daily decisions, routines, and trust, and ING OneApp has the scale to affect that experience for millions of customers. I would like to contribute with the kind of Android engineering I value most: clear user flows, reliable behavior, strong attention to detail, and a good understanding of how the mobile app fits into the wider financial experience.

Thank you for your time and consideration.

Kind regards,
Ferhat Sanli
