

Dear Hiring Manager,

I first noticed TicketSwap through a friend who was using the app, and what stayed with me was not only the idea of safer and fairer ticket exchange, but also the mobile experience itself. The Android app feels fast, simple, and focused, without unnecessary distractions. I also noticed the care put into the dark mode, especially for OLED screens, which is a small detail but a strong signal of product quality.

As an Android Developer, I have been building Kotlin-based applications with Jetpack Compose, MVVM, Retrofit, Room, Firebase, StateFlow, Coroutines, and maintainable architecture in mind. My strongest interest is not only creating screens, but connecting mobile interfaces with reliable backend data, clear state handling, and user journeys that feel smooth in real usage.

A good example of this mindset is my WhoConnected project, an Android network monitoring and device discovery app connected to a Node.js API running on a Raspberry Pi. The app communicates with the backend through REST APIs and presents scan results through a Compose interface. While it is a personal project, it reflects how I like to think: define system boundaries, structure the data flow, and turn technical behavior into a usable Android experience. I also paid attention to both light and dark mode presentation, including screenshots for both in the project README.

What interests me about TicketSwap is that the Android app sits very close to real user trust. Discovering an event, receiving alerts, buying a ticket, and accessing it at the right moment all depend on speed, clarity, and reliability. I would like to contribute to that kind of product environment, while continuing to grow on the product side, especially around experimentation, analytics, and understanding how mobile decisions affect user behavior.

Kind regards,  
Ferhat Sanli
